

Muon pair production

Muon pair production is the interaction $e^- + e^+ \rightarrow \mu^- + \mu^+$.

Define the following momentum vectors and spinors. Symbol E is beam energy. Symbol p is electron momentum $p = \sqrt{E^2 - m^2}$ where m is electron mass 0.51 MeV. Symbol ρ is muon momentum $\rho = \sqrt{E^2 - M^2}$ where M is muon mass 106 MeV. Polar angle θ is the observed scattering angle. Azimuth angle ϕ cancels out in scattering calculations.

$$\begin{array}{lll}
 p_1 = \begin{pmatrix} E \\ 0 \\ 0 \\ p \end{pmatrix} & u_{11} = \begin{pmatrix} E + m \\ 0 \\ p \\ 0 \end{pmatrix} & u_{12} = \begin{pmatrix} 0 \\ E + m \\ 0 \\ -p \end{pmatrix} \\
 \text{inbound } e^- & \text{inbound } e^- \\ \text{spin up} & & \text{inbound } e^- \\ & & \text{spin down} \\
 \\
 p_2 = \begin{pmatrix} E \\ 0 \\ 0 \\ -p \end{pmatrix} & v_{21} = \begin{pmatrix} -p \\ 0 \\ E + m \\ 0 \end{pmatrix} & v_{22} = \begin{pmatrix} 0 \\ p \\ 0 \\ E + m \end{pmatrix} \\
 \text{inbound } e^+ & \text{inbound } e^+ \\ \text{spin up} & & \text{inbound } e^+ \\ & & \text{spin down} \\
 \\
 p_3 = \begin{pmatrix} E \\ \rho \sin \theta \cos \phi \\ \rho \sin \theta \sin \phi \\ \rho \cos \theta \end{pmatrix} & u_{31} = \begin{pmatrix} E + M \\ 0 \\ p_3^z \\ p_3^x + ip_3^y \end{pmatrix} & u_{32} = \begin{pmatrix} 0 \\ E + M \\ p_3^x - ip_3^y \\ -p_3^z \end{pmatrix} \\
 \text{outbound } \mu^- & \text{outbound } \mu^- \\ \text{spin up} & & \text{outbound } \mu^- \\ & & \text{spin down} \\
 \\
 p_4 = \begin{pmatrix} E \\ -\rho \sin \theta \cos \phi \\ -\rho \sin \theta \sin \phi \\ -\rho \cos \theta \end{pmatrix} & v_{41} = \begin{pmatrix} p_4^z \\ p_4^x + ip_4^y \\ E + M \\ 0 \end{pmatrix} & v_{42} = \begin{pmatrix} p_4^x - ip_4^y \\ -p_4^z \\ 0 \\ E + M \end{pmatrix} \\
 \text{outbound } \mu^+ & \text{outbound } \mu^+ \\ \text{spin up} & & \text{outbound } \mu^+ \\ & & \text{spin down}
 \end{array}$$

The spinors are not individually normalized. Instead, a combined spinor normalization constant $N = (E + m)^2(E + M)^2$ will be used.

This is the probability density for spin state $abcd$. The formula is derived from Feynman diagrams for muon pair production.

$$|\mathcal{M}_{abcd}|^2 = \frac{e^4}{N s^2} |(\bar{u}_{3c} \gamma_\mu v_{4d})(\bar{v}_{2b} \gamma^\mu u_{1a})|^2$$

Symbol e is electron charge and

$$s = (p_1 + p_2)^2 = 4E^2$$

The expected probability density $\langle |\mathcal{M}|^2 \rangle$ is computed by summing $|\mathcal{M}_{abcd}|^2$ over all spin states and dividing by the number of inbound states. There are four inbound states.

$$\begin{aligned} \langle |\mathcal{M}|^2 \rangle &= \frac{1}{4} \sum_{a=1}^2 \sum_{b=1}^2 \sum_{c=1}^2 \sum_{d=1}^2 |\mathcal{M}_{abcd}|^2 \\ &= \frac{e^4}{4N s^2} \sum_{a=1}^2 \sum_{b=1}^2 \sum_{c=1}^2 \sum_{d=1}^2 |(\bar{u}_{3c} \gamma_\mu v_{4d})(\bar{v}_{2b} \gamma^\mu u_{1a})|^2 \end{aligned}$$

The Casimir trick uses matrix arithmetic to compute $\langle |\mathcal{M}|^2 \rangle$.

$$\langle |\mathcal{M}|^2 \rangle = \frac{e^4}{4s^2} \text{Tr} \left((\not{p}_3 + M) \gamma^\mu (\not{p}_4 - M) \gamma^\nu \right) \text{Tr} \left((\not{p}_2 - m) \gamma_\mu (\not{p}_1 + m) \gamma_\nu \right)$$

The result is

$$\langle |\mathcal{M}|^2 \rangle = e^4 \left(1 + \cos^2 \theta + \frac{m^2 + M^2}{E^2} \sin^2 \theta + \frac{m^2 M^2}{E^4} \cos^2 \theta \right)$$

For high energy experiments $E \gg M$ a useful approximation is

$$\langle |\mathcal{M}|^2 \rangle = e^4 (1 + \cos^2 \theta)$$

Cross section

The differential cross section is

$$\frac{d\sigma}{d\Omega} = \frac{\langle |\mathcal{M}|^2 \rangle}{4(4\pi\epsilon_0)^2 s}, \quad s = (p_1 + p_2)^2 = 4E^2$$

For high energy experiments we have

$$\langle |\mathcal{M}|^2 \rangle = e^4 (1 + \cos^2 \theta)$$

Hence for high energy experiments

$$\frac{d\sigma}{d\Omega} = \frac{e^4}{4(4\pi\epsilon_0)^2 s} (1 + \cos^2 \theta)$$

Noting that

$$e^2 = 4\pi\epsilon_0 \alpha \hbar c$$

we have

$$\frac{d\sigma}{d\Omega} = \frac{\alpha^2(\hbar c)^2}{4s} (1 + \cos^2 \theta)$$

Noting that

$$d\Omega = \sin \theta d\theta d\phi$$

we also have

$$d\sigma = \frac{\alpha^2(\hbar c)^2}{4s} (1 + \cos^2 \theta) \sin \theta d\theta d\phi$$

Let $S(\theta_1, \theta_2)$ be the following surface integral of $d\sigma$.

$$S(\theta_1, \theta_2) = \int_0^{2\pi} \int_{\theta_1}^{\theta_2} d\sigma$$

The solution is

$$S(\theta_1, \theta_2) = \frac{2\pi\alpha^2(\hbar c)^2}{4s} (I(\theta_2) - I(\theta_1))$$

where

$$I(\theta) = -\frac{\cos^3 \theta}{3} - \cos \theta$$

The cumulative distribution function is

$$F(\theta) = \frac{S(0, \theta)}{S(0, \pi)} = \frac{I(\theta) - I(0)}{I(\pi) - I(0)} = -\frac{\cos^3 \theta}{8} - \frac{3 \cos \theta}{8} + \frac{1}{2}, \quad 0 \leq \theta \leq \pi$$

The probability of observing scattering events in the interval θ_1 to θ_2 is

$$P(\theta_1 \leq \theta \leq \theta_2) = F(\theta_2) - F(\theta_1)$$

Let N be the total number of scattering events from an experiment. Then the number of scattering events in the interval θ_1 to θ_2 is predicted to be

$$NP(\theta_1 \leq \theta \leq \theta_2)$$

The probability density function is

$$f(\theta) = \frac{dF(\theta)}{d\theta} = \frac{3}{8} (1 + \cos^2 \theta) \sin \theta$$

Data from SLAC PEP experiment

See www.hepdata.net/record/ins216031, Table 1, $s = (29.0 \text{ GeV})^2$.

Data x and y have the following relationship with the differential cross section formula.

$$x = \cos \theta, \quad y = s \frac{d\sigma}{d \cos \theta} = 2\pi s \frac{d\sigma}{d\Omega}$$

The cross section formula is

$$\frac{d\sigma}{d\Omega} = \frac{\alpha^2}{4s} (1 + \cos^2 \theta) \times (\hbar c)^2$$

To compute predicted values \hat{y} , multiply by 10^{37} to convert square meters to nanobarns.

$$\hat{y} = 2\pi s \frac{d\sigma}{d\Omega} = \frac{\pi\alpha^2}{2} (1 + x^2) \times (\hbar c)^2 \times 10^{37}$$

The following table shows predicted values \hat{y} .

x	y	\hat{y}
-0.925	67.08	60.44
-0.85	58.67	56.10
-0.75	54.66	50.89

0.925	55.70	60.44

The coefficient of determination R^2 measures how well predicted values fit the data.

$$R^2 = 1 - \frac{\sum(y - \hat{y})^2}{\sum(y - \bar{y})^2} = 0.87$$

The result indicates that the model $d\sigma$ explains 87% of the variance in the data.

Electroweak model

The following differential cross section formula from electroweak theory results in a better fit to the data.¹

$$\frac{d\sigma}{d\Omega} = F(s)(1 + \cos^2 \theta) + G(s) \cos \theta$$

where

$$F(s) = \frac{\alpha^2}{4s} \left(1 + \frac{g_V^2}{\sqrt{2}\pi} \left(\frac{m_Z^2}{s - m_Z^2} \right) \left(\frac{sG}{\alpha} \right) + \frac{(g_A^2 + g_V^2)^2}{8\pi^2} \left(\frac{m_Z^2}{s - m_Z^2} \right)^2 \left(\frac{sG}{\alpha} \right)^2 \right)$$

$$G(s) = \frac{\alpha^2}{4s} \left(\frac{\sqrt{2}g_A^2}{\pi} \left(\frac{m_Z^2}{s - m_Z^2} \right) \left(\frac{sG}{\alpha} \right) + \frac{g_A^2 g_V^2}{\pi^2} \left(\frac{m_Z^2}{s - m_Z^2} \right)^2 \left(\frac{sG}{\alpha} \right)^2 \right)$$

¹F. Mandl and G. Shaw, *Quantum Field Theory Revised Edition*, 316.

and

$$\begin{aligned}
 g_A &= -0.5 \\
 g_V &= -0.0348 \\
 m_Z &= 91.17 \text{ GeV} \\
 G &= 1.166 \times 10^{-5} \text{ GeV}^{-2}
 \end{aligned}$$

The corresponding formula for \hat{y} is

$$\hat{y} = 2\pi [F(s)(1 + x^2) + G(s)x] \times (\hbar c)^2 \times 10^{37}$$

where $\sqrt{s} = 29 \text{ GeV}$ is the center of mass collision energy. Here are the predicted values \hat{y} based on the above formula.

x	y	\hat{y}
-0.925	67.08	65.59
-0.85	58.67	60.84
-0.75	54.66	55.07
-0.65	51.72	49.96
-0.55	43.70	45.49
-0.45	41.12	41.69
-0.35	39.71	38.53
-0.25	35.34	36.02
-0.15	33.35	34.17
-0.05	34.69	32.97
0.05	34.05	32.42
0.15	34.48	32.53
0.25	34.66	33.28
0.35	35.23	34.69
0.45	35.60	36.75
0.55	40.13	39.47
0.65	42.56	42.83
0.75	46.37	46.85
0.85	49.28	51.52
0.925	55.70	55.45

The coefficient of determination R^2 is

$$R^2 = 1 - \frac{\sum(y - \hat{y})^2}{\sum(y - \bar{y})^2} = 0.98$$

The result indicates that electroweak theory explains 98% of the variance in the data.

Notes

Here are a few notes about how the demo script works.

In component notation, traces are sums over a repeated index, in this case α .

$$\begin{aligned}\text{Tr}\left((\not{p}_3 + M)\gamma^\mu(\not{p}_4 - M)\gamma^\nu\right) &= (\not{p}_3 + M)^\alpha_\beta \gamma^{\mu\beta}_\rho (\not{p}_4 - M)^\rho_\sigma \gamma^{\nu\sigma}_\alpha \\ \text{Tr}\left((\not{p}_2 - m)\gamma_\mu(\not{p}_1 + m)\gamma_\nu\right) &= (\not{p}_2 - m)^\alpha_\beta \gamma_{\mu\rho}^\beta (\not{p}_1 + m)^\rho_\sigma \gamma_\nu^\sigma_\alpha\end{aligned}$$

To convert the above formulas to Eigenmath code, the γ tensors need to be transposed so that repeated indices are adjacent to each other. Also, multiply γ^μ by the metric tensor to lower the index.

$$\begin{aligned}\gamma^{\beta\mu}_\rho &\rightarrow \text{gammaT} = \text{transpose}(\text{gamma}) \\ \gamma^\beta_{\mu\rho} &\rightarrow \text{gammaL} = \text{transpose}(\text{dot}(\text{gmunu}, \text{gamma}))\end{aligned}$$

Define the following 4×4 matrices.

$$\begin{aligned}(\not{p}_1 + m) &\rightarrow \text{X1} = \text{pslash1} + \text{m I} \\ (\not{p}_2 - m) &\rightarrow \text{X2} = \text{pslash2} - \text{m I} \\ (\not{p}_3 + M) &\rightarrow \text{X3} = \text{pslash3} + \text{M I} \\ (\not{p}_4 - M) &\rightarrow \text{X4} = \text{pslash4} - \text{M I}\end{aligned}$$

Then

$$\begin{aligned}(\not{p}_3 + M)^\alpha_\beta \gamma^{\mu\beta}_\rho (\not{p}_4 - M)^\rho_\sigma \gamma^{\nu\sigma}_\alpha &\rightarrow \text{T1} = \text{contract}(\text{dot}(\text{X3}, \text{gammaT}, \text{X4}, \text{gammaT}), 1, 4) \\ (\not{p}_2 - m)^\alpha_\beta \gamma_{\mu\rho}^\beta (\not{p}_1 + m)^\rho_\sigma \gamma_\nu^\sigma_\alpha &\rightarrow \text{T2} = \text{contract}(\text{dot}(\text{X2}, \text{gammaL}, \text{X1}, \text{gammaL}), 1, 4)\end{aligned}$$

Next, multiply matrices and sum over repeated indices. The dot function sums over ν then the contract function sums over μ . The transpose makes the ν indices adjacent as required by the dot function.

$$\text{Tr}(\dots \gamma^\mu \dots \gamma^\nu) \text{Tr}(\dots \gamma_\mu \dots \gamma_\nu) \rightarrow \text{contract}(\text{dot}(\text{T1}, \text{transpose}(\text{T2})))$$
